Let us also look at classification within angiosperms to understand some of the concerns that influenced the classification systems. The earliest systems of classification used only gross superficial morphological characters such as habit, colour, number and shape of leaves, etc. They were based mainly on vegetative characters or on the androecium structure (system given by Linnaeus). Such systems were **artificial**; they separated the closely related species since they were based on a few characteristics. Also, the artificial systems gave equal weightage to vegetative and sexual characteristics; this is not acceptable since we know that often the vegetative characters are more easily affected by environment.

→ similar character between organisms

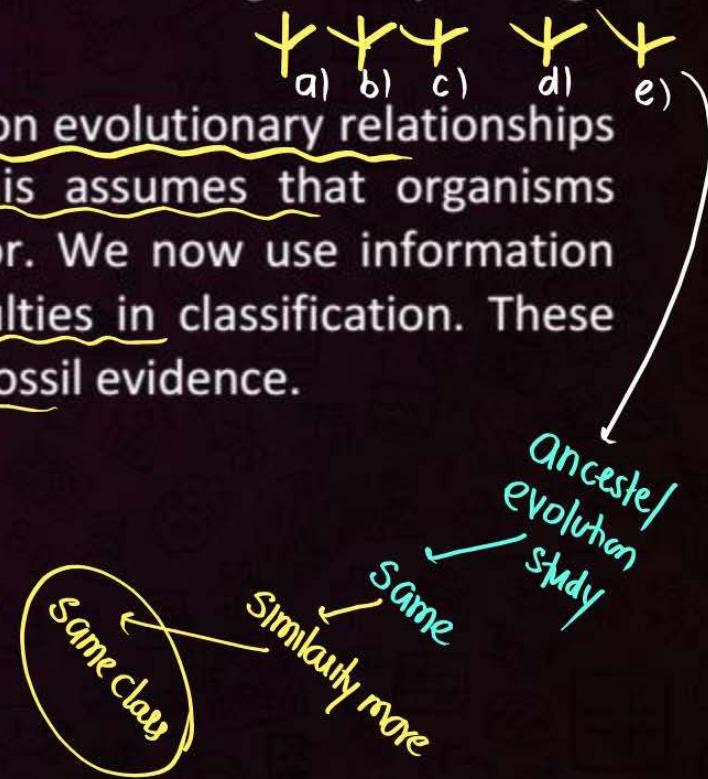

As against this, **natural classification systems** developed, which were based on natural affinities among the organisms and consider, not only the external features, but also internal features, like ^{Cell Structure} ultrastructure, anatomy, embryology and phytochemistry. Such a classification for flowering plants was given by George Bentham and Joseph Dalton Hooker.
^{Terpene, alkaloids, crystal (CaCO₃)}

no. of criteria: more.

At present **phylogenetic classification systems** based on evolutionary relationships between the various organisms are acceptable. This assumes that organisms belonging to the same taxa have a common ancestor. We now use information from many other sources too to help resolve difficulties in classification. These become more important when there is no supporting fossil evidence.

Same class

Numerical Taxonomy which is now easily carried out using computers is based on all observable characteristics. Number and codes are assigned to all the characters and the data are then processed. In this way each character is given equal importance and at the same time hundreds of characters can be considered. **Cytotaxonomy** that is based on cytological information like chromosome number, structure, behaviour and **chemotaxonomy** that uses the chemical constituents of the plant to resolve confusions, are also used by taxonomists these days.

DNA

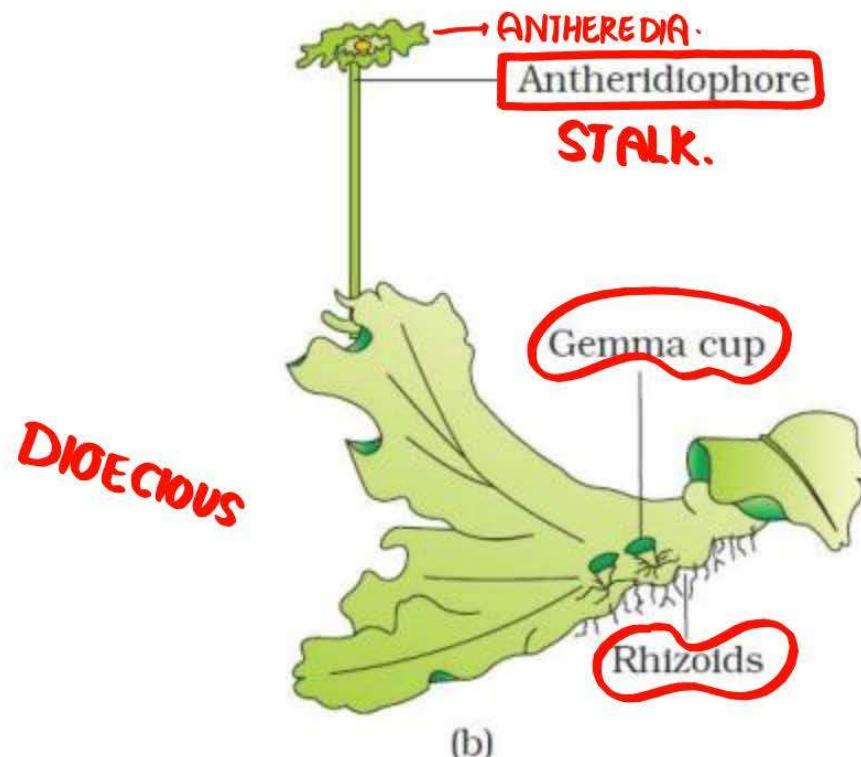

TABLE 3.1 Divisions of Algae and their Main Characteristics

Classes	Common Name	Major Pigments	Stored Food	Cell Wall	Flagellar Number and Position of Insertions	Habitat
Chlorophyceae	Green algae	Chlorophyll <i>a, b</i>	Starch	Cellulose	2-8 equal, apical	Fresh water, brackish water, salt water (MARINE)
Phaeophyceae	Brown algae	Chlorophyll <i>a, c,</i> fucoxanthin	Mannitol, laminarin	Cellulose and algin <i>Cellulose cell wall covered by algin</i>	2 unequal, lateral	Fresh water (rare) brackish water, salt water
Rhodophyceae	Red algae	Chlorophyll <i>a, d,</i> phycoerythrin	Floridean starch	Cellulose, pectin and poly sulphate esters	Absent	Fresh water (some). brackish water, salt water (most)

gametophyte

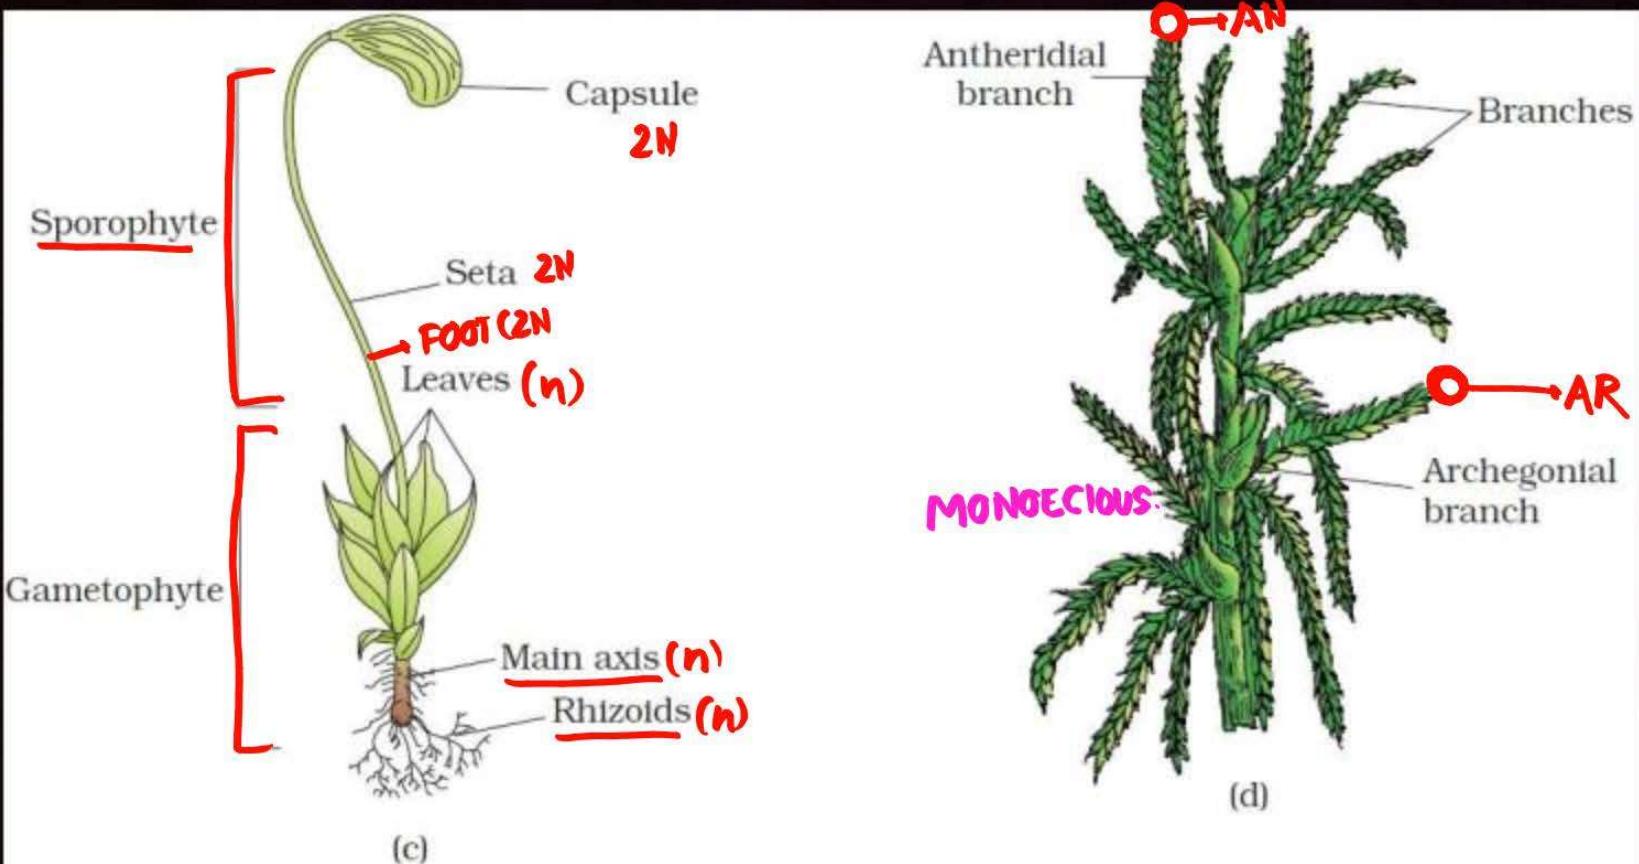

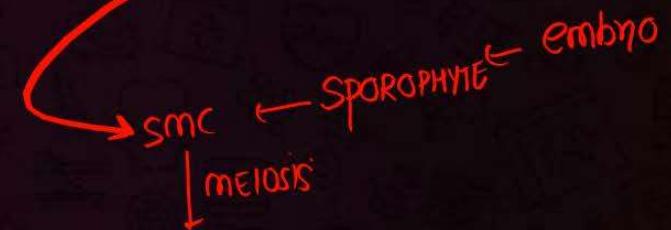

Figure 3.2 Bryophytes: A liverwort – *Marchantia* (a) Female thallus (b) Male thallus Mosses – (c) *Funaria*, gametophyte and sporophyte (d) *Sphagnum* gametophyte

The plant body of bryophytes is more differentiated than that of algae. It is thallus-like and prostrate or erect, and attached to the substratum by unicellular or multicellular rhizoids. They lack true roots, stem or leaves. They may possess root-like, leaf-like or stem-like structures. The main plant body of the bryophyte is haploid. It produces gametes, hence is called a **gametophyte**. The sex organs in bryophytes are multicellular. The male sex organ is called **antheridium**. They produce biflagellate **antherozoids**. The female sex organ called **archegonium** is flask-shaped and produces a single egg.

Male gamete

The antherozoids are released into water where they come in contact with archegonium. An antherozoid fuses with the egg to produce the zygote. Zygotes do not undergo reduction division immediately. They produce a multicellular body called a **sporophyte**. The sporophyte is not free-living but attached to the photosynthetic gametophyte and derives nourishment from it. Some cells of the sporophyte undergo reduction division (meiosis) to produce haploid spores. These spores germinate to produce gametophyte.

Bryophytes in general are of little economic importance but some mosses provide food for herbaceous mammals, birds and other animals. [Species of *Sphagnum*, a moss, provide peat that have long been used as fuel,] and as packing material for trans-shipment of living material because of their capacity to hold water. [Mosses along with lichens are the first organisms to colonise rocks and hence, are of great ecological importance. They decompose rocks making the substrate suitable for the growth of higher plants.] Since mosses form dense mats on the soil, they reduce the impact of falling rain and prevent soil erosion. The bryophytes are divided into liverworts and mosses.

herbs
sprouts
Tree
(HIGHER PLANT)

2.1 Liverworts

The liverworts grow usually in moist, shady habitats such as banks of streams, marshy ground, damp soil, bark of trees and deep in the woods. The plant body of a liverwort is thalloid, e.g., *Marchantia*. The thallus is dorsiventral and closely appressed to the substrate. The leafy members have tiny leaf-like appendages in two rows on the stem-like structures.

ROOT,
STEM,
LEAF ABSENT

PORELLA

Asexual reproduction in liverworts takes place by fragmentation of thalli, or by the formation of specialised structures called **gemmae** (sing. gemma). Gemmae are green, multicellular, asexual buds, which develop in small receptacles called gemma cups located on the thalli. The gemmae become detached from the parent body and germinate to form new individuals. During sexual reproduction, male and female sex organs are produced either on the same or on different thalli. The sporophyte is differentiated into a foot, seta and capsule. After meiosis, spores are produced within the capsule. These spores germinate to form free-living / independent gametophytes.

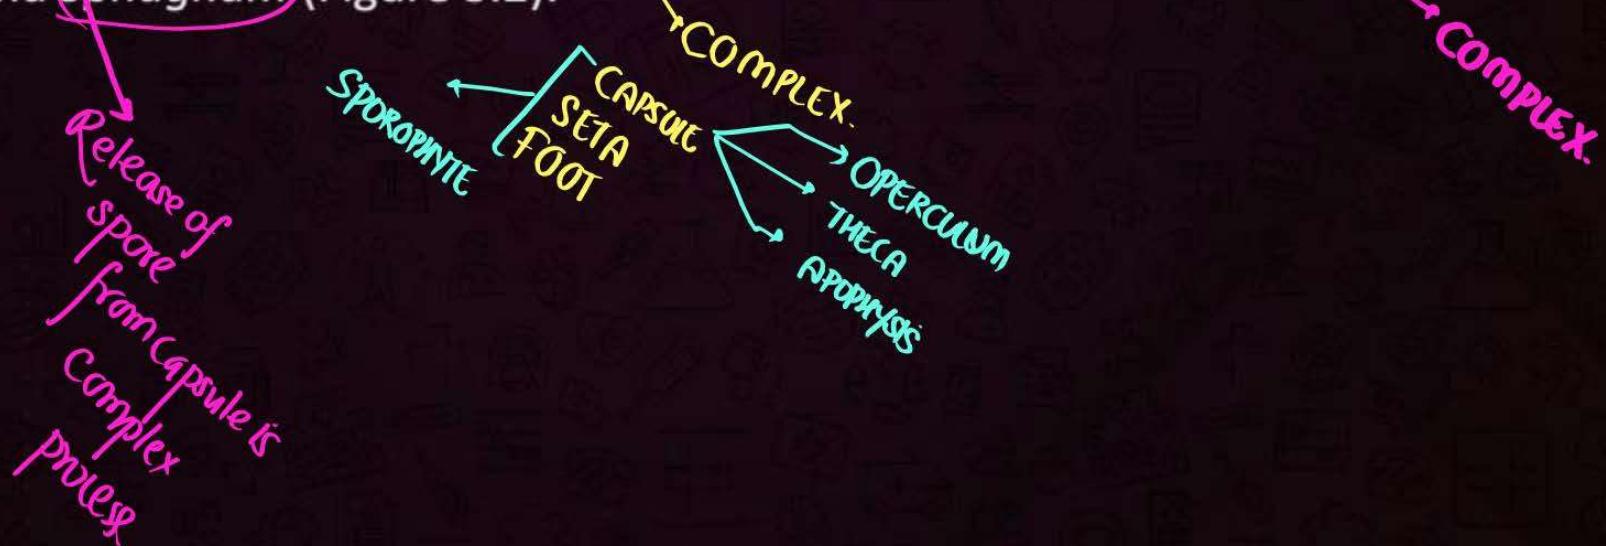

2.2. Mosses

The predominant stage of the life cycle of a moss is the gametophyte which consists of two stages. The first stage is the **protonema** stage, which develops directly from a spore. It is a creeping, green, branched and frequently filamentous stage. The second stage is the **leafy stage**, which develops from the secondary protonema as a lateral bud. They consist of upright, slender axes bearing spirally arranged leaves. They are attached to the soil through multicellular and branched rhizoids. This stage bears the sex organs.

BUDS → LEAFY GAMETOPHYTE

Vegetative reproduction in mosses is by fragmentation and budding in the secondary protonema. In sexual reproduction, the sex organs antheridia and archegonia are produced at the apex of the leafy shoots. After fertilisation, the zygote develops into a sporophyte, consisting of a foot, seta and capsule. The sporophyte in mosses is more elaborate than that in liverworts. The capsule contains spores. Spores are formed after meiosis. The mosses have an elaborate mechanism of spore dispersal. Common examples of mosses are *Funaria*, *Polytrichum* and *Sphagnum* (Figure 3.2).

P
W

3. Pteridophytes

decoration

The Pteridophytes include horsetails and ferns. Pteridophytes are used for medicinal purposes and as soil-binders. They are also frequently grown as ornamentals. Evolutionarily, they are the first terrestrial plants to possess vascular tissues – xylem and phloem. You shall study more about these tissues in Chapter 6. The pteridophytes are found in cool, damp, shady places though some may flourish well in sandy-soil conditions.

(*equisetum*)

hold soil (prevent soil erosion)

You may recall that in bryophytes the dominant phase in the life cycle is the gametophytic plant body. However, in pteridophytes, the main plant body is a sporophyte which is differentiated into true root, stem and leaves (Figure 3.3). These organs possess well-differentiated vascular tissues. The leaves in pteridophyta are small (microphylls) as in *Selaginella* or large (macrophylls) as in ferns. The sporophytes bear sporangia that are subtended by leaf-like appendages called **sporophylls**.^① In some cases sporophylls may form distinct compact structures called strobili or cones (*Selaginella*, *Equisetum*). The sporangia produce spores by meiosis in spore mother cells. The spores germinate to give rise to inconspicuous, small but multicellular, free-living, mostly photosynthetic thalloid gametophytes called **prothallus**.

PROTHALLUS

These gametophytes require cool damp, shady places to grow. Because of this specific restricted requirement and the need for water for fertilisation, the spread of living pteridophytes is limited and restricted to narrow geographical regions. The gametophytes bear male and female sex organs called antheridia and archegonia, respectively. Water is required for transfer of antherozoids – the male gametes released from the antheridia, to the mouth of archegonium. Fusion of male gamete with the egg present in the archegonium result in the formation of zygote. Zygote thereafter produces a multicellular well-differentiated sporophyte which is the dominant phase of the pteridophytes. In majority of the pteridophytes all the spores are of similar kinds; such plants are called **homosporous**.

Genera like *Selaginella* and *Salvinia* which produce two kinds of spores, macro (large) and micro (small) spores, are known as **heterosporous**. The megasporangia and microsporangia germinate and give rise to female and male gametophytes, respectively. The female gametophytes in these plants are retained on the parent sporophytes for variable periods. The development of the zygotes into young embryos take place within the female gametophytes. This event is a precursor to the **seed habit** considered an important step in evolution.

The pteridophytes are further classified into four classes: Psilopsida (*Psilotum*); Lycopsida (*Selaginella*, *Lycopodium*), Sphenopsida (*Equisetum*) and Pteropsida (*Dryopteris*, *Pteris*, *Adiantum*).

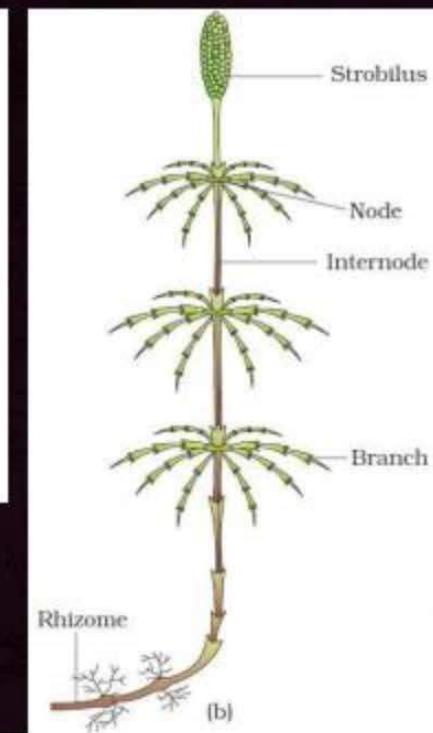

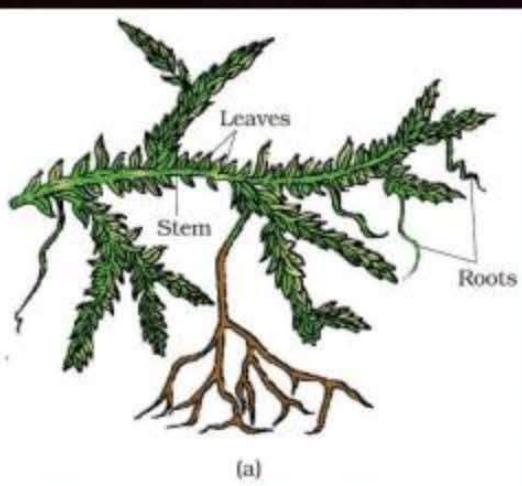

Figure 3.3 Pteridophytes : (a) *Selaginella* (b) *Equisetum* (c) Fern (d) *Salvinia*

4. Gymnosperms

The gymnosperms (*gymnos* : naked, *sperma* : seeds) are plants in which the ovules are not enclosed by any ovary wall and remain exposed, both before and after fertilisation. The seeds that develop post-fertilisation, are not covered, i.e., are naked. Gymnosperms include medium-sized trees or tall trees and shrubs (Figure 3.4). One of the gymnosperms, the giant redwood tree Sequoia is one of the tallest tree species. The roots are generally tap roots. Roots in some genera have fungal association in the form of **mycorrhiza** (*Pinus*), while in some others (*Cycas*) small specialised roots called coralloid roots are associated with N₂-fixing cyanobacteria.

Ranabaena

The stems are unbranched (*Cycas*) or branched (*Pinus*, *Cedrus*). The leaves may be simple or compound. In *Cycas* the pinnate leaves persist for a few years. The leaves in gymnosperms are well-adapted to withstand extremes of temperature, humidity and wind. In conifers, the needle-like leaves reduce the surface area. Their thick cuticle and sunken stomata also help to reduce water loss.

T
PINUS
impermeable
to H_2O

deeply
seated

TRANSPIRATION ↓

The gymnosperms are heterosporous; they produce haploid microspores and megasporangia. The two kinds of spores are produced within sporangia that are borne on sporophylls which are arranged spirally along an axis to form lax or compact strobili or cones. The strobili bearing microsporophylls and microsporangia are called microsporangiate or male strobili. The microspores develop into a male gametophytic generation which is highly reduced and is confined to only a limited number of cells. This reduced gametophyte is called a pollen grain. The development of pollen grains take place within the microsporangia. The cones bearing megasporophylls with ovules or megasporangia are called megasporangiate or female strobili.

The male or female cones or strobili may be borne on the same tree (*Pinus*).
However, in *cycas* male cones and megasporophylls are borne on different trees.
The megasporangia are clustered to form female cones. The megasporangium is a multicellular structure that bears two or more archegonia or female sex organs. The multicellular female gametophyte is also retained within megasporangium.

permanently

micropyle

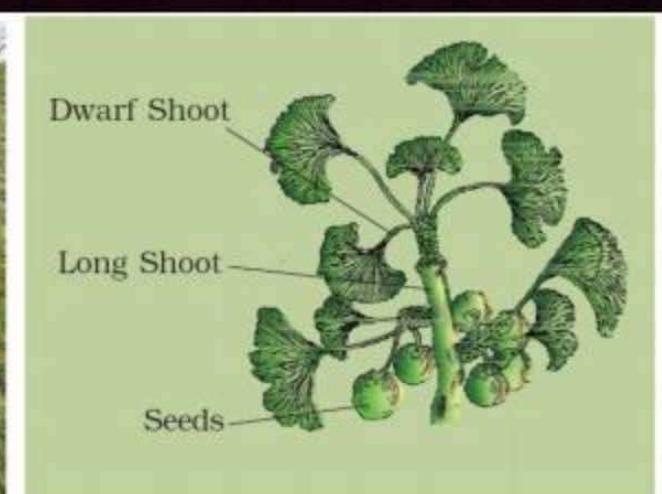

Unlike bryophytes and pteridophytes, in gymnosperms the male and the female gametophytes do not have an independent free-living existence. They remain within the sporangia retained on the sporophytes. The pollen grain is released from the microsporangium. They are carried in air currents and come in contact with the opening of the ovules borne on megasporophylls. The pollen tube carrying the male gametes grows towards archegonia in the ovules and discharge their contents near the mouth of the archegonia. Following fertilisation, zygote develops into an embryo and the ovules into seeds. These seeds are not covered.

(a)

(b)

(c)

Figure 3.4 Gymnosperms: (a) *Cycas*
(b) *Pinus* (c) *Ginkgo*

5. Angiosperms

Unlike the gymnosperms where the ovules are naked, in the angiosperms or flowering plants, the pollen grains and ovules are developed in specialised structures called **flowers**. In angiosperms, the seeds are enclosed in fruits. The angiosperms are an exceptionally large group of plants occurring in wide range of habitats. They range in size from the smallest *Wolffia* to tall trees of *Eucalyptus* (over 100 metres). They provide us with food, fodder, fuel, medicines and several other commercially important products. They are divided into two classes : the **dicotyledons** and the **monocotyledons** (Figure 3.5).

(a)

(b)

Figure 3.5 Angiosperms : (a) A dicotyledon (b) A monocotyledon

141. Read the following statements and choose the set of correct statements:

In the members of Phaeophyceae,

NEET 2024.

- A. Asexual reproduction occurs usually by biflagellate zoospores. ✓
- B. Sexual reproduction is by oogamous method only. ~~ISO, an ISO, OO~~ ✓
- C. Stored food is in the form of carbohydrates which is either mannitol or laminarin. ✓
- D. The major pigments found are chlorophyll a, c and carotenoids and xanthophyll. ✓
- E. Vegetative cells have a cellulosic wall, usually covered on the outside by gelatinous coating of algae

Choose the correct answer from the options given below:

- (1) A, B, C and D only
- (2) B, C, D and E only
- (3) A, C, D and E only
- (4) A, B, C and E only

QUESTION

A : In gymnosperms, the pollen grains are released from the microsporangium and carried by air currents.

C

R : Air currents carry the pollen grains to the mouth of archegonia where male gamete is discharged and pollen tube is ~~not~~ formed.

IC

(2023)

- 1** Both A and R are true but R is not correct explanation of A
- 2** A is true but R is false ✓

(BA)

QUESTION

(2021)

Gemmae are present in:

1 Pteridophytes

2 Some Gymnosperms

3 Some Liverworts

4 Mosses

QUESTION

Genera like *Selaginella* and *Salvinia* produce two kinds of spores. Such plants are known as:

(2021)

- 1 Heterosorus
- 2 Homosporous
- 3 Heterosporous
- 4 Homosorus

QUESTION

(2020)

Which of the following pairs is of unicellular algae?

- 1 *Gelidium* and *Gracilaria*
- 2 *Anabaena* and *Volvox*
- 3 *Chlorella* and *Spirulina*
- 4 *Laminaria* and *Sargassum*

Gelidium and *Gracilaria*

Anabaena and *Volvox*

Chlorella and *Spirulina*

Laminaria and *Sargassum*

QUESTION

(2020)

Floridean starch has structure similar to:

- 1 Amylopectin and glycogen
- 2 Mannitol and algin
- 3 Laminarin and cellulose
- 4 Starch and cellulose

QUESTION

Phycoerythrin is the major pigment in:

(2020-Covid)

- 1 Blue green algae
- 2 Green algae
- 3 Brown algae
- 4 Red algae

QUESTION

(2020)

Strobili or cones are found in:

- 1 *Pteris*
- 2 *Marchantia*
- 3 *Equisetum* & *selaginella*
- 4 *Salvinia*

QUESTION

Which of the following statements is incorrect about gymnosperms?

(2020-Covid)

- 1 Male and female gametophytes are ^{not} free living
- 2 Most of them have narrow leaves with thick cuticle
- 3 Their seeds are not covered
- 4 They are heterosporous

QUESTION

Male and female gametophytes do not have an independent free living existence in:

- 1 Algae
- 2 Angiosperms
- 3 Bryophytes
- 4 Pteridophytes

(2020-Covid)

gym & angio

QUESTION

From evolutionary point of view, retention of the female gametophyte with developing young embryo on the parent sporophyte for **some time**, is first observed in (2019)

- 1 Liverworts
- 2 Mosses
- 3 Pteridophytes
- 4 Gymnosperms

variable period

QUESTION

Pinus seed cannot germinate and establish without fungal association. This is because :

(2019)

- 1 Its embryo is immature.
- 2 It has obligate association with mycorrhizae.
- 3 It has very hard seed coat.
- 4 Its seeds contain inhibitors that prevent germination.

QUESTION

(2018)

Which one is wrongly matched?

1

Uniflagellate gametes - *Polysiphonia*
NON MOTILE (oogamous)
(RA)

2

Biflagellate zoospores - Brown algae

3

Gemma cups - *Marchantia*

4

Unicellular organism - *Chlorella*

QUESTION

(2018)

Which of the following statement is correct?

- 1 Ovules are not enclosed by ovary wall in gymnosperms
- 2 Selaginella is heterosporous, while Salvinia is ^{hetero}homosporous
- 3 Horsetails are ^{Pleido}gymnosperms
- 4 Stems are usually unbranched in both Cycas and Cedrus
^{UNB} ^(BRAN)

QUESTION

An example of colonial alga is

(2017-Delhi)

- 1 *Chlorella*
- 2 *Volvox*
- 3 *Ulothrix*
- 4 *Spirogyra*

QUESTION

(2017-Delhi)

Select the mismatch:

- 1 *Pinus* - ~~Dioecious~~
2 *Cycas* C - Dioecious
3 *Salvinia* C - Heterosporous
4 *Equisetum* C - Homosporous

QUESTION

Double fertilisation is exhibited by

(2017-Delhi)

- 1** Gymnosperms
- 2** Algae
- 3** Fungi
- 4** Angiosperms

QUESTION

Life cycle of *Ectocarpus* and *Fucus* respectively are:

(2017-Delhi)

- 1 Haplontic, Diplontic
- 2 Diplontic, Haplodiplontic
- 3 Haplo-diplontic, Diplontic *B,P* *Gym,angio*
- 4 Haplo-diplontic, Haplontic

QUESTION

Zygotic meiosis is characteristic of:

[OS] (2017-Delhi)

- 1 *Marchantia* (BRYOP)
- 2 *Fucus* (DIPLONTIC)
- 3 *Funaria* (Bryop)
- 4 *Chlamydomonas* ✓
(Haplontic).
~~Haploid~~

QUESTION

Conifers are adapted to tolerate extreme environmental conditions because of: (2016 - II)

- 1 Thick cuticle
- 2 Presence of vessels
- 3 Broad hardy leaves
- 4 Superficial stomata
SUNKEN.
